

Kd-trees

- Invented in 1970s by Jon Bentley
- Binary data algorithm for storing data structures in computer science.
- Name originally meant “3d-trees, 4d-trees, etc” where k was the # of dimensions
- Now, people say “kd-tree of dimension d ”
- Idea: Each level of the tree compares against 1 dimension.

k-d tree example

Dataset

x1	x2
1	9
2	3
4	1
3	7
5	4
6	8
7	2
8	8
7	9
9	6

k-d tree algorithm organizes the dataset as tree

- 1) Pick a feature at random, say X_1
- 2) Find Median of X_1 and split dataset based on the median of X_1

(1,9), (2,3), (4,1), (3,7), (5,4), (6,8), (7,2), (8,8), (7,9), (9,6)

Half the dataset end up on each side

k-d tree algorithm cont..

3) Take the median of X_2 and split data again

(1,9), (2,3), (4,1), (3,7), (5,4), (6,8), (7,2), (8,8), (7,9), (9,6)

Finding KNN for new data point z ($x_1=7, x_2=5$)

- Search logic will be via matching the new Z point to the tree logic
- Pick the best Neighbour based on euclidean distance
- This process can repeated N times to find N neighbours
- Note k -d tree doesn't always find optimum NN but its fast
